2007

Abstract: A number of classical and not so classical problems in number theory concern finding polynomials with integer coefficients that are of small norm. These include old chestnuts like the Merit Factor problem, Lehmer's Conjecture and Littlewood's (other) Conjecture.

Let

$$\mathcal{Z}_n := \left\{ \sum_{i=0}^n a_i z^i : a_i \in \mathbb{Z} \right\}$$

denote the set of algebraic polynomials of degree at most n with integer coefficients and let \mathcal{Z} denote the union.

Let

$$\mathcal{L}_n := \left\{ \sum_{i=0}^n a_i z^i : a_i \in \{-1, 1\} \right\}$$

denote the set of polynomials of degree at most n with coefficients from $\{-1, 1\}$. Call such polynomials **Littlewood polynomials**.

The **supremum norm** of a polynomial p on a set A is defined as

$$\|p\|_A := \sup_{z \in A} |p(z)|.$$

For positive α , the L_α norm on the boundary of the unit disk is defined by

$$\|p\|_\alpha := \left(\frac{1}{2\pi} \int_0^{2\pi} |p(e^{i\theta})|^\alpha d\theta \right)^{1/\alpha}.$$

For

$$p(z) := a_n z^n + \cdots + a_1 z + a_0$$

the L_2 norm on D is also given by

$$\|p\|_2 = \sqrt{|a_n|^2 + \cdots + |a_1|^2 + |a_0|^2}.$$

The two interesting limiting cases give

$$\lim_{\alpha \rightarrow \infty} \|p\|_{\alpha} = \|p\|_D =: \|p\|_{\infty}$$

and

$$\lim_{\alpha \rightarrow 0} \|p\|_{\alpha} = \exp \left(\frac{1}{2\pi} \int_0^{2\pi} \log |p(e^{i\theta})| d\theta \right).$$

The latter is the **Mahler measure** denoted by $M(p)$. Jensen's theorem for

$$p_n(z) := a(z - \alpha_1)(z - \alpha_2) \cdots (z - \alpha_n)$$

gives

$$M(p_n) = |a| \prod_{|\alpha_i| \geq 1} |\alpha_i|.$$

Mahler's measure is multiplicative:

$$M(pq) = M(p)M(q)$$

Problem 1. Littlewood's Problem in L_∞ (1950?). Find the polynomial in \mathcal{L}_n that has smallest possible supremum norm on the unit disk.

Show that there exist positive constants c_1 and c_2 so that for any n it is possible to find $p_n \in \mathcal{L}_n$ with

$$c_1\sqrt{n} \leq |p_n(z)| \leq c_2\sqrt{n}$$

for all complex z with $|z| = 1$.

Littlewood, in part, based his conjecture on computations of all such polynomials up to degree twenty.

Odlyzko has now done 200 MIPS years of computing on this problem

A Related Erdős's Problem in L_∞ .

Show that there exists a positive constant c_3 so that for all n and all $p_n \in \mathcal{L}_n$ we have $\|p_n\|_D \geq (1 + c_3)\sqrt{n}$.

Merit Factor Problems (1950?). The L_4 norm computes algebraically. If

$$p(z) := \sum_{k=0}^n a_k z^k$$

has real coefficients then

$$p(z)p(1/z) = \sum_{k=-n}^n c_k z^k$$

where the **acyclic autocorrelation coefficients**

$$c_k = \sum_{j=0}^{n-k} a_j a_{j+k} \quad \text{and} \quad c_{-k} = c_k$$

and

$$\|p(z)\|_4^4 = \|p(z)p(1/z)\|_2^2 = \sum_{k=-n}^n c_k^2.$$

The **merit factor** is defined by

$$MF(p) = \frac{\|p\|_2^4}{\|p\|_4^4 - \|p\|_2^4}$$

or equivalently

$$MF(p) = \frac{n + 1}{2 \sum_{k>0} c_k^2}.$$

The merit factor is a useful normalization. It tends to give interesting sequences integer limits and makes the expected merit factor of a polynomial with ± 1 coefficients 1.

The Rudin-Shapiro polynomials have merit factors that tend to 3.

Problem 2. Merit Factor Problem.

Find the polynomial in \mathcal{L}_n that has smallest possible L_4 norm on the unit disk.

Show that there exists a positive constant c_4 so that for all n and all $p_n \in \mathcal{L}_n$ we have

$$L_4(p_n) \geq (1 + c_4)\sqrt{n}.$$

Equivalently show that the Merit Factor is bounded above.

The Related Barker Polynomial Problem. For $n > 12$ and $p_n \in \mathcal{L}_n$ show that

$$L_4(p_n) > ((n + 1)^2 + 2n)^{1/4}.$$

Equivalently show that at least one non trivial autocorrelation coefficient is strictly greater than 1 in modulus.

This is much weaker than the Merit Factor Problem.

- Find sequences that have analysable Merit Factors

Theorem . For q an odd prime, the Turyn type polynomials

$$R_q(z) := \sum_{k=0}^{q-1} \binom{k + [q/4]}{q} z^k$$

where $[\cdot]$ denotes the nearest integer, satisfy

$$\|R_q\|_4^4 = \frac{7q^2}{6} - q - \frac{1}{6} - \gamma_q$$

and

$$\gamma_q := \begin{cases} h(-q)(h(-q) - 4) & \text{if } q \equiv 1, 5 \pmod{8} \\ 12(h(-q))^2 & \text{if } q \equiv 3 \pmod{8}, \\ 0 & \text{if } q \equiv 7 \pmod{8}. \end{cases}$$

Thus these polynomials have merit factors asymptotic to 6.

Golay, Høholdt and Jensen, and Turyn (and others) show that the merit factors of cyclically permuted character polynomials associated with non-principal real characters (the Legendre symbol) vary asymptotically between $3/2$ and 6.

Several authors have conjectured this is best possible. For example in 1983 Golay wrote:

“[Six] is the highest merit factor obtained so far for systematically synthesized binary sequences, and the eventuality must be considered that no systematic synthesis will ever be found which will yield higher merit factors.”

And in 1988 Høholdt and Jensen wrote:

“We therefore make a new conjecture concerning the merit factor problem, namely, that asymptotically the maximum value of the merit factor is 6 and hence that offset Legendre sequences are optimal.”

A really interesting observation made by Tony Kirilusha and Ganesh Narayanaswamy as summer students at the University of Richmond of Jim Davis suggested that one should try building on Turyn's construction by appending the initial part of Turyn's sequence to the end.

Their suggestion was wrong but the intuition was good. To see what is happening one needs to look at sequences of length 100,000 or greater.

We conjecture there exist sequences of Turyn type polynomials (with modification) that have merit factors growing like 6.3. (Joint work with Choi and Jedwab).

Basically one rotates the Fekeete polynomials by 22 percent and adds 5.7 percent of the initial terms to the end.

The numbers are compelling!!

Merit Factor Problem Restated.

For a sequence of length $n+1$

$$\{a_0, a_1, a_2, \dots, a_n\} \quad a_k = \pm 1$$

the **acyclic autocorrelation coefficients**

$$c_k := \sum_{j=0}^{n-k} a_j a_{j+k} \quad \text{and} \quad c_{-k} = c_k$$

and the **Merit factor**

$$MF := \frac{n+1}{2 \sum_{k>0} c_k^2}.$$

For any (all) n , **maximize this!**

- This has been called the "hardest combinatorial optimization problem known."

- Best merit factors have been computed up to length 59. This is by variations on branch and bound algorithms (with huge effort).
- The “landscape” for best merit factors is very irregular. We suspect that most heuristics are wrong.
- All Golay pairs are known up to length 100.
- Barker polynomials (all autocorrelations of size at most 1) are known not to exist up to 10^{20} – far past computational ranges.

- One ambition is to map out the best merit factor space probabilistically up to degree 100 or so.
- This is done with a mix of hill climbing and simulated annealing. (And a lot of cluster computing.)
- It works surprisingly well. (Joint with Ferguson and Knauer).

Problem 3. Lehmer's Problem (1933).

Show that a (non-cyclotomic) polynomial p with integer coefficients has Mahler measure at least 1.1762.... (This latter constant is the Mahler measure of $1 + z - z^3 - z^4 - z^5 - z^6 - z^7 + z^9 + z^{10}$.)

A conjecture of similar flavour (implied by the above) is

Conjecture of Schinzel and Zassenhaus (1965). *There is a constant c so that any non-cyclotomic polynomial p_n of degree n with integer coefficients has at least one root of modulus at least c/n .*

The best partials are due to Smyth.

If p is a non-reciprocal polynomial of degree n then at least one root ρ satisfies

$$\rho \geq 1 + \frac{\log \phi}{n}$$

where $\phi = 1.3247\dots$ is the smallest Pisot number, namely the real root of $z^3 - z - 1$.

The number ϕ is also the smallest measure of a non-reciprocal polynomial.

Theorem 1 (Hare, Mossinghoff and PB) *Suppose f is a monic, nonreciprocal polynomial with integer coefficients satisfying $f \equiv \pm f^* \pmod{m}$ for some integer $m \geq 2$. Then*

$$M(f) \geq \frac{m + \sqrt{m^2 + 16}}{4}, \quad (1)$$

and this bound is sharp when m is even.

Corollary 1 *If f is a monic, nonreciprocal polynomial whose coefficients are all odd integers, then*

$$M(f) \geq M(x^2 - x - 1) = (1 + \sqrt{5})/2.$$

Theorem 2 (Dobrowolski, Mossinghoff and PB) *Suppose f is a monic polynomial with all odd integer coefficients of degree n that does not have measure 1.*

a] *Schinzel and Zassenhaus holds for this class with at least one root of modulus at least $(1 + .31/n)$.*

b] *If f is irreducible then Lehmer's conjecture holds for this class and the measure must be at least 1.495.*

A Related Problem of Mahler's. *For each n find the polynomials in \mathcal{L}_n that have largest possible Mahler measure. Analyse the asymptotic behaviour as n tends to infinity.*

Multiplicity of Zeros of Height One Polynomials. *What is the maximum multiplicity of the vanishing at 1 of a height 1 polynomial ?*

Multiplicity of Zeros in \mathcal{L}_n . *What is the maximum multiplicity of the vanishing at 1 of a polynomial in \mathcal{L}_n ?*

Problem 4. Littlewood's 22nd Problem

“If the n_m are integral and all different, what is the lower bound on the number of real zeros of

$$\sum_{m=1}^N \cos(n_m \theta)??$$

Possibly $N - 1$, or not much less.”

Littlewood in his 1968 monograph “Some Problems in Real and Complex Analysis” poses this research problem, which appears to still be open.

In fact no progress appears to have been made on this in the last half century. Until now.

Theorem 3 *It is possible to construct cosine polynomials with the n_m integral and all different, so that the number of real zeros of*

$$\sum_{m=1}^N \cos(n_m \theta)$$

is

$$O\left(N^{9/10}\right).$$

We also prove in a positive direction.

Denote the number of zeros of T in the period $[-\pi, \pi)$ by $N(T)$.

Theorem 4 *Suppose the set $\{a_j : j \in \mathbb{N}\} \subset \mathbb{R}$ is finite and the set $\{j \in \mathbb{N} : a_j \neq 0\}$ is infinite. Let*

$$T_n(t) = \sum_{j=0}^n a_j \cos(jt).$$

Then

$$\lim_{n \rightarrow \infty} N(T_n) = \infty.$$

One of our main tools for this, not surprisingly, is the resolution of the Littlewood Conjecture.

The next two results SHOULD be straightforward corollaries of the above result
(????)

Theorem 5 *Let A_N denote the the lower bound on the number of zeros in period $[-\pi, \pi)$ of all N term cosine sums of the form*

$$\sum_{m=1}^N \cos(n_m \theta)$$

then

$$\lim_{n \rightarrow \infty} B_n = \infty.$$

As an answer to a question of B. Conrey.

Theorem 6 *Let B_N denote the the lower bound on the number of zeros in period $[-\pi, \pi)$ of all N term cosine sums*

of the form

$$\sum_{m=1}^N \pm \cos(n\theta)$$

then

$$\lim_{n \rightarrow \infty} A_n = \infty.$$

Lemma 1 Let $\lambda_0 < \lambda_1 < \dots < \lambda_m$ be nonnegative integers and let

$$S_m(t) = \sum_{j=0}^m A_j \cos(\lambda_j t).$$

Then

$$\int_{-\pi}^{\pi} |S_m(t)| dt \geq \frac{1}{80} \sum_{j=0}^m \frac{|A_{m-j}|}{j+1}.$$

Littlewood's 22nd Problem

Problem 1 *“If the n_m are integral and all different, what is the lower bound on the number of real zeros of $\sum_{m=1}^N \cos(n_m\theta)$ Possibly $N - 1$, or not much less.”*

In terms of reciprocal polynomials one is looking for a reciprocal polynomial with coefficients 0 and 1 with $2n$ terms and $n-1$ or fewer zeros.

Even achieving $n-1$ is fairly hard.

An exhaustive search up to $2n = 32$ yielded only the 2 examples below with $n-1$ zeros of modulus one and none with $n-2$ or fewer zeros.

There were only 11 more examples with exactly n zeros. It is hard to see how one might generate infinitely many examples or indeed why Littlewood made his conjecture.

$$x^{27} + x^{26} + x^{25} + x^{19} + x^{18} + x^{17} + x^{15} + x^{14} + x^{13} + x^{12} + x^{10} + x^9 + x^8 + x^2 + x + 1$$

and

$$\begin{aligned}
& x^{31} + x^{30} + x^{29} + x^{28} + x^{27} + x^{26} + \\
& x^{25} + x^{24} + x^{23} + x^{20} + x^{19} + x^{17} + x^{14} \\
& + x^{12} + x^{11} + x^8 + x^7 + x^6 + x^5 + x^4 + \\
& x^3 + x^2 + x + 1
\end{aligned}$$

The following is a reciprocal polynomial with 32 terms and exactly 14 zeros of modulus 1. So it corresponds to a cosine sum of 16 terms with 14 zeros in $[-\pi, \pi)$. In other words the sharp version of Littlewood's conjecture is false. (Though barely.)

$$\begin{aligned}
& 1 + x + x^2 + x^4 + x^3 + x^5 + x^6 + x^7 + x^8 + \\
& x^9 + x^{12} + x^{13} + x^{14} + x^{15} + x^{16} + x^{18} + x^{20}
\end{aligned}$$

$$\begin{aligned} &+x^{22} + x^{23} + x^{24} + x^{25} + x^{26} + x^{29} + \\ &x^{30} + x^{31} + x^{32} + x^{33} + x^{34} + x^{35} + x^{36} + \\ &x^{37} + x^{38} \end{aligned}$$

The following is a reciprocal polynomial with 280 terms and 52 zeros of modulus 1. So it corresponds to a cosine sum of 140 terms with 52 zeros in $[-\pi, \pi)$. In other words the sharp version of Littlewood's conjecture is false. Though this time by a margin.

It was found by a version of the greedy algorithm (and some guessing). There

is no reason to believe it is a minimal example.

$$(1 + x + x^2 + x^4 + x^3 + x^5 + x^6 + x^7 + x^8 + x^9 + x^{10} + x^{11} + x^{12} + x^{13} + x^{19} + x^{14} + x^{15} + x^{17} + x^{18} + x^{16} + x^{20} + x^{21} + x^{22} + x^{23} + x^{24} + x^{25} + x^{26} + x^{27} + x^{28} + x^{29} + x^{30} + x^{31} + x^{32} + x^{33} + x^{34} + x^{35} + x^{36} + x^{37} + x^{38} + x^{39} + x^{40} + x^{41} + x^{42} + x^{43} + x^{44} + x^{45} + x^{46} + x^{47} + x^{48} + x^{49} + x^{50} + x^{51} + x^{52} + x^{53} + x^{54} + x^{55} + x^{56} + x^{57} + x^{58} + x^{59} + x^{60} + x^{61} + x^{62} + x^{63} + x^{64} + x^{65} + x^{66} + x^{67} + x^{68} + x^{69} + x^{70} + x^{71} + x^{72} + x^{73} + x^{74} + x^{75} + x^{76} + x^{78} + x^{79} +$$

$$\begin{aligned} &x^{80} + x^{81} + x^{82} + x^{83} + x^{77} + x^{84} + x^{85} + \\ &x^{86} + x^{87} + x^{88} + x^{89} + x^{90} + x^{91} + x^{92} + \\ &x^{93} + x^{94} + x^{95} + x^{96} + x^{97} + x^{98} + x^{99} + \\ &x^{100} + x^{101} + x^{102} + x^{103} + x^{104} + x^{105} + \\ &x^{106} + x^{107} + x^{108} + x^{109} + x^{110} + x^{111} + \\ &x^{112} + x^{113} + x^{114} + x^{115} + x^{116} + x^{117} + \\ &x^{118} + x^{119} + x^{120} + x^{121} + x^{122} + x^{123} + \\ &x^{129} + x^{130} + x^{131} + x^{132} + x^{133} + x^{135} + \\ &x^{136} + x^{137} + x^{138} + x^{139} + x^{140} + x^{142} + \\ &x^{144} + x^{146} + x^{149} + x^{150} + x^{154} + x^{155} + \\ &x^{158} + x^{160} + x^{162} + x^{164} + x^{165} + x^{171} + \\ &x^{166} + x^{167} + x^{169} + x^{168} + x^{172} + x^{173} + \\ &x^{174} + x^{175} + x^{181} + x^{182} + x^{183} + x^{184} + \\ &x^{185} + x^{186} + x^{187} + x^{188} + x^{189} + x^{190} + \end{aligned}$$

$$\begin{aligned} &x^{191} + x^{192} + x^{193} + x^{194} + x^{195} + x^{196} + \\ &x^{197} + x^{198} + x^{199} + x^{200} + x^{201} + x^{202} + \\ &x^{203} + x^{204} + x^{205} + x^{206} + x^{207} + x^{208} + \\ &x^{209} + x^{210} + x^{211} + x^{212} + x^{213} + x^{214} + \\ &x^{215} + x^{216} + x^{217} + x^{218} + x^{219} + x^{220} + \\ &x^{221} + x^{222} + x^{223} + x^{224} + x^{225} + x^{226} + \\ &x^{227} + x^{228} + x^{230} + x^{231} + x^{232} + x^{233} + \\ &x^{234} + x^{235} + x^{229} + x^{236} + x^{237} + x^{238} + \\ &x^{239} + x^{240} + x^{241} + x^{242} + x^{243} + x^{244} + \\ &x^{245} + x^{246} + x^{247} + x^{248} + x^{249} + x^{250} + \\ &x^{251} + x^{252} + x^{253} + x^{254} + x^{255} + x^{256} + \\ &x^{257} + x^{258} + x^{259} + x^{260} + x^{261} + x^{262} + \\ &x^{263} + x^{264} + x^{265} + x^{266} + x^{267} + x^{268} + \\ &x^{269} + x^{270} + x^{271} + x^{272} + x^{273} + x^{274} + \end{aligned}$$

$$\begin{aligned} &x^{275} + x^{276} + x^{277} + x^{278} + x^{279} + x^{280} + \\ &x^{281} + x^{282} + x^{283} + x^{284} + x^{285} + x^{286} + \\ &x^{287} + x^{288} + x^{289} + x^{290} + x^{291} + x^{292} + \\ &x^{293} + x^{294} + x^{295} + x^{296} + x^{297} + x^{298} + \\ &x^{299} + x^{300} + x^{301} + x^{302} + x^{303} + x^{304}) \end{aligned}$$

Auxilliary Functions

The key is to construct n term cosine sums that are large most of the time.

Lemma 2 *There is a constant C such that for all n and $\alpha > 1$ there is a sequence a_0, \dots, a_n with each $a_i \in \{0, 1\}$ such that*

$$\text{meas}\{t \in [-\pi, \pi) : |P_n(t)| \leq \alpha\} \leq C\alpha n^{-1/2}.$$

where

$$P_n(t) = \sum_{j=0}^n a_j \cos(jt).$$

The Main Theorem

Theorem 7 *It is possible to construct cosine polynomials with the n_m integral and all different, so that the number of real zeros of*

$$\sum_{m=1}^N \cos(n_m \theta)$$

is

$$O\left(N^{9/10} \log^{1/5}(N)\right).$$

The proof follows immediately from the following lemma and Lemma 2.

(Take $m := N+1$, $n = m^{2/5} \log^{-4/5}(m)$,
 $\alpha = n^{1/4}$ and $\beta = C\alpha n^{-1/2} = Cn^{-1/4}$.)

Lemma 3 *Let $m \leq n$,*

$$D_m(t) := \sum_{j=0}^m \cos(jt),$$

$$P_n(t) := \sum_{j=0}^n a_j \cos(jt), \quad a_j \in \{0, 1\}.$$

Suppose $\alpha \geq 1$ and

$$\text{meas}\{t \in [-\pi, \pi) : |P_n(t)| \leq \alpha\} \leq \beta.$$

Let $S_m := D_m - P_n$. Then the number of zeros of S_m in $[-\pi, \pi)$ is at most

$$\frac{c_1 m}{\alpha} + c_2 m \beta + c_3 n m^{1/2} \log m,$$

where c_1 , c_2 , and c_3 are absolute constants.

For this we need the following consequence of the Erdős-Turán Theorem.

Lemma 4 *Let*

$$S_m(t) = \sum_{j=0}^n a_j \cos(jt), \quad a_j \in \{0, 1\}.$$

Denote the number of zeros of S_m in $[\alpha, \beta] \subset [-\pi, \pi)$ by $N([\alpha, \beta])$. Then

$$N([\alpha, \beta]) \leq c_4 m(\beta - \alpha) + c_4 \sqrt{m} \log m,$$

where c_4 is an absolute constant.

Average Number of Zeros

Lemma 5 *Suppose that p is a polynomial of degree exactly n and p has k zeros of modulus greater than 1 and j zeros of modulus 1 then for any m*

$$(z^m p(z) \pm p^*(z))$$

has degree $m+n$ and at least $m+n - 2k$ roots of modulus 1.

Proof. Rouché's theorem shows that

$$(1 + \epsilon)z^m p(z) \pm p^*(z)$$

and

$$z^m p(z)$$

have the same number of roots inside the unit disk. Note that $|p(z)| = |p^*(z)|$ for $|z| = 1$.

So with $\epsilon = 0$, $z^m p(z) \pm p^*(z)$ has all but k zeros in the closed unit disk.

Now use the fact that $z^m p(z) \pm p^*(z)$ is reciprocal so has the same number of zeros of modulus less than 1 as of modulus greater than 1.

Lemma 6 *Suppose that p is a polynomial of degree exactly n and $p(0) \neq 0$. Consider*

$$P := (z^m p(z) \pm p^*(z))$$

and

$$Q := (z^m p^*(z) \pm p(z)).$$

with the same choice of sign (ie the cos case and the sin case). Suppose P has j_1 zeros of modulus 1 and Q has j_2 zeros of modulus 1. Then

$$j_1 + j_2 \geq 2m.$$

Proof. Use the previous lemma and note that if p has k zeros of modulus greater than 1 and j zeros of modulus 1 then p^* has $n - k - j$ zeros of modulus greater than 1 and j zeros of modulus 1.

Note that if $M := (m - n)/2 \geq 1$ with M an integer then

$$C := \sum_{i=M}^{n+M} a_i \cos it$$

and

$$S := \sum_{i=M}^{n+M} a_i \sin it$$

correspond to

$$P(z) := (z^m p(z) \pm p^*(z))$$

with

$$p(z) = \sum_{i=0}^n a_i z^i.$$

Also zeros of P of modulus 1 correspond (with the same count) to zeros of the trigonometric polynomials C and S in the period $[0, \pi)$.

Lemma 7 *Suppose $a_{n+M} \neq 0$. Consider*

$$C(t) := \sum_{i=M}^{n+M} a_i \cos it$$

and

$$C^*(t) := \sum_{i=M}^{n+M} a_{(n+M+M-i)} \cos it$$

which reverses the coefficients.

Let w_1 be the number of zeros of C in the period $[0, \pi)$ and let w_2 be the number of zeros of C^ in the period $[0, \pi)$ then*

$$w_1 + w_2 \geq m \geq n + 1.$$

Furthermore $w_1 \geq m$ and $w_2 \geq m$.

Averaging over any reasonable class of sums gives:

Lemma 8 *The average number of zeros over the classes*

$$\left\{ \sum_{i=1}^n \pm \cos it \right\}$$

and

$$\left\{ \sum_{i=1}^n \delta_i \cos it, \delta_i \in 0, 1 \right\}$$

is at least $n/2$.
